

OCR quality is not what limits the dataset

Share of the 1,346 biographical notices from which each field could be read, by quartile of the notice's mean per-word OCR confidence (median 0.920, range 0.670–0.997). Recovery barely moves. The cleanest quartile records a birth year least often, which is a composition effect and not a legibility one — those notices are the longest in the volume (592 characters at the median against 352 in the worst quartile); they simply do not print a date.
