

The projection says hubs cluster together; the raw graph says the opposite

Degree assortativity in each network. In the two-mode graph it is -0.14: a body with many members is mostly joined by people who belong to little else, which is what a membership list looks like. In the projection it is +0.35, but that is largely the projection talking — turning one body of n members into a clique gives all n the same high degree and makes them each other's neighbours. Prefer the two-mode figure; the projection's number is about the method.
