

Natives broker as much as colonists, from fewer memberships and further out

59 colonists and 45 natives, all placed by a body they belonged to and all in the co-membership giant component — the only comparison fig. 55 permits. Betweenness do not separate the two sides. Closeness, co-members and bodies joined do: a native belongs to about a third fewer bodies and sits further from everyone else. The pairing is the point — the same share of brokerage on fewer ties means a native's memberships each carry more of it, which is what a tie that crosses the colonial line rather than running along it would do. With samples this small and this zero-inflated, read a null as 'no difference these numbers can detect' rather than as no difference.
