

Europeans and Tunisians belonged to the same bodies less often than chance

Co-membership ties among the 266 people whose community the entry settles and who share a body with another such person: 795 ties. Cross-community ties run 23% below the random benchmark, and Tunisian-Tunisian ties at 2.2 times it. Assortativity $r = 0.23$ — mild segregation, not separation. Fig. 62 puts the same question to the colonist/native coding, against a null that shuffles labels rather than assuming independence, and finds the gap wider.
