

Europeans and Tunisians belonged to the same bodies less often than chance

Co-membership ties among the 267 people whose community the entry settles and who share a body with another such person: 801 ties. Cross-community ties run 26% below the random benchmark, and Tunisian-Tunisian ties at 2.3 times it. Assortativity $r = 0.26$ — mild segregation, not separation. Fig. 62 puts the same question to the colonist/native coding, against a null that shuffles labels rather than assuming independence, and finds the gap wider.
