

How a person was identified moves this measure more than which side he was on

Mean betweenness in the co-membership giant component, for people placed on the colonial line by different kinds of evidence. Among colonists alone — one side of the line, so nothing about the colonial order can explain it — those placed by a communal body sit on 3.8 times as many paths as those placed by a birthplace ($p < 0.001$). The evidence that identifies a person and the ties that give him a network position are the same ties. Only the lower two bars hold that constant, and between them the gap is 0.0052 ($p = 0.467$). Every comparison in figs. 56 to 63 is drawn on the matched basis for this reason.
