

Colonists and natives belonged to the same bodies far less often than chance

Every pair of placed people who share a body, by whether the pair crosses the colonial line: 130 of 923 pairs do, 14.1%. The grey distribution is 2,000 relabellings that keep every body and every body's size and shuffle only who is a colonist and who is a native; it centres on 29.6%. The observed share falls below all but a handful of them ($p < 0.001$). This is the finding the rest of this group does not make: the line is not in what the volume awarded or printed, and barely in where people sit in the network — it is in association itself.
